1 Introduction

1.1 Trial information

This is a 30-week randomised, double-blind, double-dummy, active-controlled, multi-centre, multinational trial, four-armed, parallel-group trial comparing semaglutide 0.5 mg and 1.0 mg once weekly against sitagliptin 100 mg once-daily.

Primary objective

To compare the effect of once-weekly dosing of two dose levels of semaglutide versus sitagliptin 100 mg once-daily on glycaemic control after 30 weeks of treatment.

To further detail the primary objective an estimand is defined which is an efficacy estimand. The scientific question is:

- What is the treatment difference between semaglutide and sitagliptin at week 30 for all randomised subjects if all subjects completed treatment and did not initiate rescue medication
- The population is defined by the inclusion/exclusion criteria of the trial
- The primary endpoint is change from baseline in HbA_{1c} after 30 weeks of treatment
- Only data collected before the occurrence of the intercurrent events *initiation of rescue medication* and *discontinuation of trial product* are used in the analysis.

Secondary objectives

To compare the effects of once-weekly dosing of two dose levels of semaglutide versus sitagliptin 100 mg once-daily after 30 weeks of treatment on:

- Inducing and maintaining weight loss
- Other parameters of efficacy, safety and tolerability

An estimand similar to the one for the primary objective is defined for the secondary objective as addressed by weight loss, however with ‘change from baseline in HbA_{1c} after 30 weeks’ replaced by ‘change from baseline in body weight after 30 weeks of treatment’.

1.2 Scope of the statistical analysis plan

This SAP is based on the protocol “Efficacy and safety of semaglutide once-weekly versus sitagliptin once-daily as add-on to metformin in subjects with type 2 diabetes”, version 3.0, and amendment 3. The SAP is relevant both for the analysis of data for the entire trial population and for the analysis of the China cohort by it self. See Section [2.7](#).

2 Statistical considerations

2.1 General considerations

Results from the statistical analysis will generally be presented by two-sided confidence intervals with a confidence level of 95% and associated p-value. Superiority will be formulated and tested as one-sided hypotheses at a 2.5% significance level. Non-inferiority between two treatments will be evaluated by comparing the upper limit of the associated two-sided 95% confidence interval for the difference with the pre-defined non-inferiority margin.

The two sitagliptin/semaglutide placebo groups will be pooled in all outputs if not otherwise specified.

When grouping or analysing data by country, subjects from Hong Kong and Taiwan will be grouped with Chinese subjects if not otherwise specified. The same is done when grouping or analysing by region China/Other where subjects from South Africa, Korea, Brazil and Ukraine will be analysed together in the group referred to as “Other”.

Data transformations

A number of the continuous parameters will be log-transformed prior to statistical analysis. The output tables and figures will show the results of the analysis back-transformed to the original scale, implying that log-treatment-differences are reported as treatment ratios. Confidence intervals for the treatment ratios will be calculated as exponentiated upper and lower limits for log-treatment difference confidence intervals. The standard errors (SE) of the back-transformed mean and ratio to baseline estimates are also provided; these SEs are calculated using the delta-method (first order Taylor approximation), whereby the SE on the original scale is calculated as the product of the SE on log-scale and the exponentiated estimate of the mean (geometric mean).

Handling of missing data

In the case of missing data no general imputation will be performed for the analyses, unless otherwise specified. If an assessment has been made both at screening and randomisation, the value from the randomisation visit will be used as the baseline value. If the value measured at the randomisation visit is missing and the assessment also has been made at screening, then the screening value will be used as the baseline value.

Laboratory values below the lower limit of quantification (LLOQ) will be set to $\frac{1}{2}$ LLOQ.

The primary analysis model will be the mixed model for repeated measurements (MMRM), see Section [2.4](#) for further details. One of the assumptions behind MMRM is that the missing data mechanism is missing at random (MAR). This means that given the observed data, the mechanism

generating missing values is independent of the unobserved data, that is the missing data. The MMRM rely on the MAR assumption for generating unbiased estimates of treatment differences.

Based on previous semaglutide trials in subjects with type 2 diabetes, the treatment discontinuation rate from randomised treatment and trial withdrawal is expected to be about 20%. The treatments in this trial should be effective, given the historical documentation, and this should minimise treatment discontinuation due to ineffective therapy. The main reasons for treatment discontinuation are expected to be AEs, ineffective therapy and non-eligibility (subjects randomised although not fulfilling inclusion/exclusion criteria). Treatment discontinuation due to non-eligibility can be regarded as missing completely at random (MCAR), i.e. it does not depend on the observed or missing data values. This category of missing data is not expected to introduce bias in the estimated treatment differences. Treatment discontinuation due to lack of efficacy is expected to be reflected in the observed data obtained prior to the discontinuation from randomised treatment, and the corresponding missing data can therefore be assumed as MAR to some extent. Missing data due to AEs is expected to be similar between groups except for, potentially, a slightly higher incidence in the semaglutide treatment group due to gastrointestinal side effects. Together with potential withdrawals from trial due to the own will of the subject, the MAR assumption may be less adequate for this category of drop-outs.

Several different sensitivity analyses described in subsequent sections will be used to investigate whether the results from the MMRM approach are robust towards deviations from the assumption of MAR.

2.2 Sample size calculation

The primary objective is to compare the effect of two dose levels of semaglutide once-weekly treatment (0.5 mg or 1.0 mg) with sitagliptin 100 mg on the primary endpoint, change from baseline in HbA_{1c} after 30 weeks of treatment. In the power calculations below it is presumed that in the analysis the two sitagliptin/semaglutide placebo groups will be pooled assuming no correlation between endpoints and placebo volume.

At the time of finalising the first version of the protocol, the regulatory guidance in China was to have 300 subjects in region China treated with semaglutide. To ensure an adequate and robust evaluation of safety and efficacy in the subjects from China 300 subjects completing treatment with semaglutide is used. In the following, subjects from Hong Kong and Taiwan will be grouped with the Chinese subjects and referred to as region China. Assuming a treatment discontinuation rate of 25% in this region and considering the 2:2:1:1 randomisation, this means that 600 subjects need to be randomised in region China. Trial NN9535-4114 is a multi-regional clinical trial, and 258 subjects are planned to be randomised outside region China as has already been approved by local authorities for these countries. For some countries the allocated subject number is required to

support local NDA submissions. In total, 858 subjects are planned to be randomised in a 2:2:1:1 manner. Assuming that 20% of all randomised subjects discontinue randomised treatment, and further taking the assumption that these subjects are excluded from the per protocol (PP) analysis set, 228 subjects in each group are expected to be included in the PP analysis set.

In total six confirmatory hypotheses are to be tested (see Section 2.4). The six hypothesis tests are assumed to be independent and for each of the hypotheses the power calculation is based on a t-statistic under the assumption of a one-sided test of size 2.5%.

Using a non-inferiority margin of 0.3%-point, a standard deviation (SD) of 1.1%-point and a total of 228 subjects per group in the PP analysis set will give 90% marginal power to conclude HbA_{1c} non-inferiority for the comparison of a semaglutide dose vs. sitagliptin 100 mg if the true HbA_{1c} treatment difference (semaglutide minus sitagliptin) is as low as -0.03 %-point. Thereby, the overall power to demonstrate HbA_{1c} non-inferiority for the two dose levels of semaglutide vs. sitagliptin will be at least 80%, even if the true treatment difference for the low dose comparison is as low as -0.03 %-point. With 286 subjects per group in the full analysis set (FAS), a marginal power of at least 90% for demonstrating HbA_{1c} superiority, for any dose of the two dose level comparisons, is obtained if the true treatment difference is as low as -0.30%-point.

For change in body weight, using a SD of 4 kg and 286 subjects per group, a marginal power of at least 90% for demonstrating superiority for the comparison of a semaglutide dose vs. sitagliptin 100 mg is obtained if the true treatment difference is as low as -1.09 kg body weight.

In SUSTAIN 2, the mother trial of NN9535-4114, semaglutide showed marked and significant reductions in HbA_{1c} and body weight vs sitagliptin at week 56. The change over time in HbA_{1c} and body weight in SUSTAIN 2 showed marked reductions in both endpoints already at week 30 which supports the above mentioned true treatment differences for trial NN9535-4114.

2.3 Definition of analysis sets

The following analysis sets are defined in accordance with the ICH-E9 guideline⁵⁸.

Full Analysis Set (FAS): includes all randomised subjects. Subjects in the FAS will contribute to the evaluation “as randomised”.

Per Protocol (PP) Analysis Set:

Includes all subjects in the FAS who fulfil the following criteria:

- have not violated any inclusion criteria
- have not fulfilled any exclusion criteria
- have a non-missing HbA_{1c} measurement at screening and /or randomisation
- have at least 23 weeks actual treatment weeks of exposure
- have at least one non-missing HbA_{1c} measurement after 23 actual weeks of exposure

Subjects in the PP Analysis Set will contribute to the analysis “as treated”.

Safety Analysis Set (SAS): includes all subjects exposed to at least one dose of trial product. Subjects in the SAS will contribute to the evaluation based on the trial product received for the majority of the period they were on treatment. This will be referred to as contributing to the evaluation “as treated”.

Before data are locked for statistical analysis, a review of all data will take place. Any decision to exclude a subject or single observations from the statistical analysis is the joint responsibility of the members of the internal study group. Exclusion of data from analyses will be used restrictively and normally no data should be excluded from the FAS. The subjects or observations to be excluded, and the reasons for their exclusion must be documented and signed by those responsible before database lock. The subjects and observations excluded from analysis sets, and the reason for this, will be described in the CTR.

Data selections and observation periods

Subjects and data to be used in an analysis will be selected in a two-step manner.

- Firstly, subjects will be selected based on the specified analysis set
- Secondly, data points on the selected subjects from first step will be selected based on the specified observation period

Definition of the observation periods:

In-trial: This observation period represents the time period where subjects are considered to be in the trial after randomisation, regardless of discontinuation of trial product or initiation of rescue medication. The in-trial observation period starts at randomisation (as registered in IWRS) and ends at the date of:

- The last direct subject-site contact, which is scheduled to take place 5 weeks after planned last dose of trial product at a follow-up visit
- Withdrawal for subjects who withdraw their informed consent

- The last subject-investigator contact as defined by the investigator for subjects who are lost to follow-up
- Death for subjects who dies before any of the above

For subjects not randomised but exposed to trial product the in-trial periods starts at the date of first dose of trial product

On-treatment: This observation period represents the time period where subjects are considered treated with trial product. The observation period is a sub-set of the in-trial observation period. It starts at the date of first dose of trial product. Two slightly different end dates will be needed to cover all assessments appropriately according to the flow chart. For adjudicated events, ECG's and AEs including hypoglycaemic episodes, the observation period ends at the first date of any of the following:

- the follow-up visit (V10)
- the follow-up prematurely discontinuation visit (V10A)
- the last date on trial product + 42 days
- the end-date for the in-trial observation period

The follow-up visit is scheduled to take place 5 weeks after the last date on trial product corresponding to approximately five half-lives of subcutaneous semaglutide. The visit window for the follow-up visit is + 7 days, which is the reason for the 42 days specified in the bullet above. Hence, for those assessments this period reflects the period in which subjects are exposed.

For efficacy and other safety assessments (laboratory assessments, physical examination and vital signs) the observation period ends at the last date on trial product + 7 days in accordance with trial flow chart and assessment times. This ascertainment window corresponds to the dosing interval and will be used to avoid attenuation of a potential treatment effect on endpoints for which the effect is reversible shortly after treatment discontinuation. Hence, for those assessments this period reflects the period in which subjects are treated.

On-treatment without rescue medication: This observation period is a sub-set of the on-treatment observation period, where subjects are considered treated with trial product, but have not initiated any rescue medications. Specifically it starts at date of first dose of trial product and the observation period ends at the first date of any of the following:

- the last dose of trial product +7 days
- initiation of rescue medication

The 'on-treatment without rescue medication' observation period will be the primary observation period for efficacy evaluations. The in-trial observation period will be considered supportive for efficacy evaluation. Safety will be evaluated based on the in-trial and the on-treatment observation periods unless otherwise specified.

For subjects who have no post-baseline scheduled assessments available in the on-treatment without rescue period, the baseline value will be carried forward to the first scheduled visit for the associated endpoint to ensure that all randomised subjects will contribute to the statistical analysis. This will not be done for the PRO assessments which are only taken at baseline and the week 30 visit.

Data points collected outside an observation period will be treated as missing in the analysis. Baseline data will always be included in an observation period. For adjudicated events, the onset date will be the EAC adjudicated onset date.

2.4 Primary endpoint

The primary endpoint is change from baseline in HbA_{1c} after 30 weeks of treatment. In the analysis the two sitagliptin/semaglutide placebo groups will be pooled assuming no correlation between HbA_{1c} change after 30 weeks and placebo volume.

The primary endpoint will be based on FAS using data from the 'on-treatment without rescue medication' observation period in a Mixed Model for Repeated Measures (MMRM). A restricted maximum likelihood (REML) will be used. The model will include all post baseline HbA_{1c} measurements collected at scheduled visits up to and including week 30 data as dependent variables. The independent effects included in the model will be treatment and region China/Other as fixed effects and baseline response as covariate, all nested within visit. An unstructured covariance matrix will be employed for measurements within the same subjects, assuming that measurements across subjects are independent. Regarding missing data this analysis approach relies on the assumption that data are missing at random (MAR). From this model, the two dose level estimated treatment differences between s.c. semaglutide versus sitagliptin at week 30 will be presented together with associated two-sided 95% confidence intervals and unadjusted two sided p-values (nominal alpha=0.05) for testing non-inferiority and superiority. In order to preserve the overall type 1 error the conclusion of non-inferiority and superiority with treatment of each semaglutide dose versus sitagliptin after 30 weeks will be evaluated hierarchically according to the sequence below, and starting with the first. In this testing sequence it is necessary to fulfil the test criteria, which is to reject the corresponding null hypothesis in order to go to the next step. If the corresponding null hypothesis is not rejected, the testing will stop and no further conclusions will be drawn.

The following ordering in the statistical test sequence will be used:

1. Non-inferiority in change in HbA_{1c} for semaglutide 1.0 mg vs. sitagliptin

2. Non-inferiority in change in HbA_{1c} for semaglutide 0.5 mg vs. sitagliptin
3. Superiority in change in HbA_{1c} for semaglutide 1.0 mg vs. sitagliptin
4. Superiority in change in body weight for semaglutide 1.0 mg vs. sitagliptin
5. Superiority in change in body weight for semaglutide 0.5 mg vs. sitagliptin
6. Superiority in change in HbA_{1c} for semaglutide 0.5 mg vs. sitagliptin

Non-inferiority will be concluded if the upper limit of the two-sided 95% confidence interval for the estimated difference in HbA_{1c} between semaglutide and sitagliptin is less than 0.3%. Superiority for either change in HbA_{1c} or change in body weight will be claimed if the upper limit of the two-sided 95% confidence interval for the estimated difference is below 0% or 0 kg respectively.

When establishing non-inferiority the analysis will be based on the full analysis set (FAS) and supplemented by an analysis with the per protocol population using the data from the 'on treatment without rescue medication' observation period as supportive evidence. The FAS population will be used in the analysis when concluding superiority.

Sensitivity analysis

To investigate the sensitivity of the main results, complimentary and separate analyses for primary endpoint and the confirmatory secondary endpoint will be performed, using the FAS only, except for HbA_{1c}, where the PP analysis set will be used in a sensitivity analysis regarding the non-inferiority evaluation. These analyses will investigate the sensitivity of the results due to the impact of missing values.

The primary analysis regarding non-inferiority of the primary endpoint change in HbA_{1c} after 30 weeks will also be performed separately based on the data in the PP analysis set only.

The primary endpoint and the secondary confirmatory endpoint will be evaluated in the following sensitivity analyses:

- An analysis of covariance (ANCOVA) model will be analysed with imputation of missing values according to the last observation carried forward (LOCF) method based on the FAS and using the data from the 'on-treatment without rescue medication' observation period. The model will include terms for treatment, region China/Other, and the corresponding baseline value as a covariate. The response variable will be the last available value obtained within the 30 weeks period of the trial
- The MMRM will be analysed based on all data from the 'in-trial' observation period
A MMRM model will be analysed based on data only from subjects that completed treatment without receiving rescue treatment and who has a valid HbA_{1c} assessment at visit 9 (week 30). The model will include terms for treatment, region China/Other, and the corresponding baseline value as a covariate.

A pattern mixture model based on the FAS using the ‘on-treatment without rescue medication’ observation period approach mimicking an ITT scenario where withdrawn subjects are assumed to be switched to a treatment inferior to the control treatment after treatment discontinuation will be performed for evaluation of non-inferiority for the primary endpoint change in HbA_{1c} at 30 weeks.

- In the first step intermittent missing values are imputed using a Markov Chain Monte Carlo (MCMC) method, in order to obtain a monotone missing data pattern. This imputation is done for each treatment group separately and 500 copies of the dataset will be generated.
- In the second step, for each of the 500 copies of the dataset, an analysis of variance model with the same factors as the primary model, and baseline HbA_{1c} and HbA_{1c} at 4 weeks (Visit 3) as covariate is fitted to the change in HbA_{1c} from baseline to 8 weeks (Visit 5) for the sitagliptin group only. The estimated parameters, and their variance, from this model are used to impute missing value at 8 weeks for subjects in all treatment groups, based on region China/Other and HbA_{1c} at baseline and 4 weeks.
- In the third step, for each of the 500 copies of the dataset, missing HbA_{1c} values at 12 weeks (Visit 6) are imputed in the same way as for 8 weeks. Now the imputations are based on an analysis of variance model with the same factors and the HbA_{1c} values at baseline, 4 weeks and 8 weeks as covariates, fitted to the control group.
- This stepwise procedure is then repeated sequentially over the available planned visits, adding one visit in each step until the last planned visit at 30 weeks (Visit 9).
- For each subject with imputed values in the investigational treatment groups, a value of 0.3% (the non-inferiority limit) is added to the change in HbA_{1c} at 30 weeks.
- For each of the complete data sets, the change from baseline to week 30 is analysed using an analysis of variance model with the same set of factors and the baseline HbA_{1c} value as a covariate.
- The estimates and standard deviations for the 500 data sets are pooled to one estimate and associated standard deviation using Rubin’s rule (page 255-257)⁵⁹ From these pooled estimates the confidence interval for the treatment differences and the associated p-value are calculated. The upper limit of the two sided 95% confidence interval will be compared to the non-inferiority limit of 0.3%.

A pattern mixture model approach mimicking an ITT scenario where subjects after initiation of rescue medication or premature treatment discontinuation are assumed to be switched to the control treatment after treatment discontinuation will be performed separately for the evaluation of superiority in the primary endpoint change in HbA_{1c} and change in body weight at 30 weeks. The same types of approach as used for the non-inferiority assessment in change in HbA_{1c} will be employed, see above. However, the step where 0.3%, the non-inferiority limit, is added to the change in HbA_{1c} at 30 weeks will not be performed in this sensitivity analysis.

Furthermore to align with recent phase 3b trials evaluating safety and efficacy of semaglutide s.c., the following sensitivity analyses have been added:

- Tipping-point analysis (pattern mixture model like) based on the FAS using the 'on-treatment without rescue medication' observation period. In this analysis, subjects from the semaglutide group under investigation with missing observations will be given a penalty, i.e., it is assumed that subjects with missing observations who are randomised to semaglutide will receive a treatment that is worse than subjects with observed values who are randomised to semaglutide. The idea is to gradually increase the penalty to evaluate at which level the superiority/non-inferiority conclusion of the analyses in terms of statistical significance is changed for each of the two semaglutide dose levels separately. The tipping point is the penalty level, at which the magnitude of efficacy reduction in subjects with missing data creates a shift in the treatment effect of semaglutide from being statistically significantly better than sitagliptin to being non-statistically significantly better for the superiority test and similarly for the non-inferiority test. Technically, this analysis will be implemented in the following way:
 - Intermittent missing values are imputed using a Markov Chain Monte Carlo (MCMC) method, in order to obtain a monotone missing data pattern. This imputation is done for each of the treatment groups separately and 500 copies of the dataset will be generated.
 - A sequential regression approach for imputing monotone missing values at planned visits will be implemented starting with the first visit after baseline and sequentially continuing to the last planned visit at week 30. A model used to impute missing values at each planned visit will be fitted for each of the treatment groups using observed data. The model will include stratification factor region China/Other as a categorical effect and baseline and post-baseline HbA_{1c} values observed or imputed prior to the visit in question as covariates. This step is similar to the detailed description given for the pattern mixture model approach described above.
 - Subsequently, increasing penalty values will be added at week 30 to imputed observations in the semaglutide group under investigation. Specifically, when evaluating treatment differences involving the 0.5 mg semaglutide group, only subjects in this group are given a penalty, and vice versa for treatment differences involving the 1.0 mg semaglutide group. For each penalty and each of the 500 complete data set, HbA_{1c} at week 30 will be analysed using an ANCOVA with treatment, and the stratification factor (region China/other) as categorical effects and baseline HbA_{1c} as a covariate. Rubin's rules will be used to combine the analysis results in order to draw inference.
- Retrieved drop-out analysis based on the FAS using post-baseline measurements up to and including week 30 from the in-trial observation period. Missing data will be imputed using the same approach as described for the tipping point analysis above. However, the imputation will be done within the same group defined not only by the randomised treatment (semaglutide (0.5mg or 1.0 mg) /sitagliptin) but also by the status of treatment completion (still on randomised treatment at week 30 yes/no). It is hereby assumed that the likely values of what the missing data would have been if available are best described by information

from subjects who at week 30 are similar in terms of randomised treatment and treatment completion status. The analysis model for the retrieved drop-out analysis is the same as for the tipping point analysis. This analysis could be considered addressing a treatment policy estimand. The retrieved drop-out is carried out for the superiority testing only.

In [Table 1](#) below a schematic overview of the different sensitivity analyses is provided.

Table 1 Summary of statistical analyses of the primary endpoint (HbA_{1c})

Population	Period	Statistical model	Imputation ¹⁾	Hypothesis to be tested
Primary non-inferiority analysis				
FAS	On-treatment without rescue medication	MMRM ²⁾	Baseline values will be carried forward to week 4 for subjects with missing week 4 values.	Non-inferiority
Primary superiority analysis				
FAS	On-treatment without rescue medication	MMRM ²⁾	Baseline values will be carried forward to week 4 for subjects with missing week 4 values.	Superiority
Sensitivity analyses				
PP	On-treatment without rescue medication	MMRM	Baseline values will be carried forward to week 4 for subjects with missing week 4 values.	Non-inferiority

Complete cases	On-treatment without rescue medication	MMRM	Not applicable	Superiority
FAS	On-treatment without rescue medication	ANCOVA ⁴⁾	Last observation carried forward for subjects with missing value at week 30	Superiority
FAS	In-trial	MMRM	Baseline values will be carried forward to week 4 for subjects with missing week 4 values	Superiority
FAS	On-treatment without rescue medication	Pattern mixture model using an ANCOVA ⁴⁾	Multiple imputation	Non-inferiority
FAS	On-treatment without rescue medication	Pattern mixture model using an ANCOVA ⁴⁾	Multiple imputation	Superiority
FAS	On-treatment without rescue medication	Tipping point analysis using an ANCOVA ⁴⁾⁵⁾ model	Multiple imputation	Non-inferiority
FAS	On-treatment without rescue medication	Tipping point analysis using an ANCOVA model ⁴⁾	Multiple imputation	Superiority
FAS	In-trial	Retrieved dropout analysis, using an ANCOVA	Multiple imputation	Superiority

		model ³⁾⁴⁾		
--	--	-----------------------	--	--

- 1) If a subject is missing baseline assessment the screening assessment will be used as the baseline assessment. If no measurement(s) have been obtained, at or prior to randomisation, the baseline value will be left missing.
- 2) MMRM model will be used to estimate the efficacy estimand
- 3) Retrieved dropout analysis, using an ANCOVA model, will be used to estimate the treatment policy estimand
- 4) Baseline and week 30 measurements will be used in the analysis
- 5) The non-inferiority margin of 0.3 is added as a penalty to imputed values in the semaglutide treatment groups

2.5 Secondary endpoints

The planned secondary endpoints used to support the primary and secondary objectives will be analysed as outlined in this section.

2.5.1 Confirmatory secondary endpoints

Weight loss

A confirmatory secondary variable is change in body weight after 30 weeks of treatment. This variable will be analysed in the same type of model as the primary endpoint although with baseline body weight as covariate and with similar sensitivity analyses.

In [Table 2](#) an overview of the sensitivity analyses for the confirmatory secondary endpoint is provided.

Table 2 Summary of statistical analyses of confirmatory secondary endpoint (Body weight)

Population	Period	Statistical model	Imputation ¹⁾	Hypothesis to be tested
Confirmatory analysis				
FAS	On-treatment without rescue medication	MMRM ²⁾	Baseline values will be carried forward to week 4 for subjects with missing week 4 values.	Superiority
Sensitivity analyses				
Complete cases	On-treatment without rescue medication	MMRM	Not applicable	Superiority
FAS	On-treatment without rescue medication	ANCOVA ⁴⁾	Last observation carried forward for subjects with missing value at week 30	Superiority
FAS	In-trial	MMRM	Baseline values will be carried forward to week 4 for subjects with missing week 4 values	Superiority
FAS	On-treatment without rescue medication	Pattern mixture model using an ANCOVA model ⁴⁾	Multiple imputation	Superiority
FAS	On-treatment without rescue	Tipping point analysis using an ANCOVA	Multiple imputation	Superiority

	medication	model ⁴⁾		
FAS	In-trial	Retrieved dropout analysis, using an ANCOVA model ^{3) 4)}	Multiple imputation	Superiority

1) If a subject is missing baseline assessment the screening assessment will be used as the baseline assessment. If no measurement(s) have been obtained, at or prior to randomisation, the baseline value will be left missing.

2) MMRM model will be used to estimate the efficacy estimand

3) Retrieved dropout analysis, using an ANCOVA model, will be used to estimate the treatment policy estimand

4) Baseline and week 30 measurements will be used in the analysis

2.5.2 Supportive secondary endpoints

2.5.2.1 Efficacy endpoints

All efficacy endpoints in this section will be summarised and evaluated using the FAS.

Continuous variables

Change from baseline to week 30 in:

- FPG
- Insulin
- C-peptide
- glucagon
- pro-insulin
- pro-insulin/insulin ratio
- HOMA-B
- HOMA-IR
- fasting blood lipids (total cholesterol, LDL-cholesterol, VLDL-cholesterol, HDL-cholesterol, triglycerides and free fatty acids)
- BMI
- waist circumference
- systolic and diastolic blood pressure

- hsCRP

will all be analysed based on the same observation period and type of model as the primary endpoint, but with the associated baseline value as a covariate.

Except for FPG, BMI, waist circumference, and blood pressure the values of the variables will be log transformed subject to analysis.

Beta-cell function

Beta-cell function (fasting HOMA-B and fasting HOMA-IR) will be calculated based on fasting insulin and FPG. The calculation will be done at the same time points as for fasting insulin and FPG samples.

The calculation of the fasting HOMA endpoints will be done as follows:

Fasting HOMA-B (%) = $20 \times \text{fasting insulin } [\mu\text{U/ml}] / (\text{FPG} [\text{mmol/l}] - 3.5)$

Fasting HOMA-IR (%) = $\text{fasting insulin } [\mu\text{U/ml}] \times \text{FPG } [\text{mmol/l}] / 22.5$

PRO outcomes

The PRO outcome endpoints:

- PRO questionnaire outcome DTSQs (individual items and treatment satisfaction score (6 of the 8 items summed)), and
- PRO questionnaire outcome SF-36v2™ short Form health survey: Total scores (physical component and mental component) and scores from the 8 domains will be analysed separately using the ANCOVA model based on the data from the on-treatment without rescue medication observation period. Factors in the model will be treatment and region China/Other. The baseline value of the corresponding endpoint will be used as covariate in the analysis model.

7-point profile

Subjects will be asked to perform SMPG measurements as described in the protocol Section 8.5.1.5.

The endpoints from the 7-point profiles that will be analysed at week 30 are:

- Mean of the 7-point profile, defined as the area under the profile, calculated using the trapezoidal method, divided by the measurement time
- Mean increment over all meals

The mean of the 7-point profile and the mean of the post prandial increments at week 30 will be analysed separately with the same data and type of methods as primary endpoint but with the corresponding baseline assessment as a covariate.

Response in HbA_{1c} and/or weight loss after 30 weeks

The secondary variables related to fixed response in HbA_{1c} and/or weight loss at 30 weeks will be:

- Responder in HbA_{1c} after 30 weeks of treatment (yes/no) defined as HbA_{1c} <7.0% (<53 mmol/mol) – ADA target
- Responder in HbA_{1c} after 30 weeks of treatment (yes/no) defined as HbA_{1c} ≤6.5% (48 mmol/mol) – AACE target
- Weight loss ≥5%
- Weight loss ≥10%
- HbA_{1c} <7.0% (53 mmol/mol) without severe or confirmed symptomatic hypoglycaemia (plasma glucose ≤3.1 mmol/L) and no weight gain

All these variables will be analysed based on the ‘on-treatment without rescue medication’ observation period separately in the same type of logistic regression model. The model will include factors for treatment and region China/Other. For the two responder in HbA_{1c} endpoints, baseline HbA_{1c} will be included in the model as a covariate, whereas for the weight responder endpoint (≥5% and ≥10% weight loss), baseline weight will be included instead. For the composite endpoint (cf. last bullet), both baseline HbA_{1c} and baseline weight will be included.

Missing response data at 30 weeks will be imputed from respectively the MMRM used for the primary analysis of HbA_{1c} and the confirmatory secondary endpoint change in body weight at 30 weeks. The results will be described by the odds ratio and the associated 95% confidence interval for the odds ratio.

2.5.2.2 Safety endpoints

The safety endpoints will be evaluated based on SAS using both the on-treatment observation period and the in-trial observation period unless otherwise stated.

The following secondary endpoints are used to support the safety objectives:

- Number of treatment emergent AEs during 30 weeks of treatment
- Number of treatment emergent severe or BG confirmed symptomatic hypoglycaemic episodes during 30 weeks of treatment
- Treatment emergent severe or BG confirmed symptomatic hypoglycaemic episodes during 30 weeks of treatment (yes/no)

Change in safety endpoints assessed from baseline to 30 weeks of treatment and/or follow up:

- Haematology
- Biochemistry
- Calcitonin
- Urinalysis
- UACR
- Pulse

- ECG evaluation
- Physical examination evaluation
- Eye examination

Occurrence of semaglutide antibodies during 35 weeks of study duration (yes/no):

- Anti-semaglutide antibodies
 - Anti-semaglutide antibodies with in vitro neutralising effect
 - Anti-semaglutide antibodies cross reacting with endogenous GLP-1
 - Cross reacting antibodies with in vitro neutralising effect to endogenous GLP-1

Anti-semaglutide antibody level during and after 30 weeks of treatment

All safety endpoints will be summarised and evaluated by descriptive statistics using the SAS.

Adverse events

The following endpoint related to adverse events is used to support the safety objective;

- Number of treatment emergent adverse events (TEAEs)

A treatment-emergent AE is an event that has onset date (or increase in severity) during the on-treatment observation period. These will therefore be referred to as ‘on-treatment AEs’ hereafter. On-treatment adverse events are summarised descriptively in terms of the number of subjects with at least one event (N), the percentage of subjects with at least one event (%), the number of events (E) and the event rate per 100 years (R). These summaries are replicated by outputs including all ‘in-trial’ adverse events (i.e., adverse events with onset date [or increase in severity] during the ‘in-trial’ observation period). Adverse events with onset after the end of the ‘in-trial’ observation period will be reported in a listing. The development over time in gastrointestinal AEs will be presented graphically.

The most frequent adverse events will be defined as preferred terms (PTs) that are experienced by at least 5% of the subjects in any of the treatment arms.

All AEs will be coded using the most recent version of the Medical Dictionary for Regulatory Activities (MedDRA) coding.

Pulse

Pulse will be analysed separately using an analysis similar to the primary analysis of the primary endpoint. However, this analysis will be based on SAS using the data from the on-treatment observation period but with the pulse value at baseline as a covariate.

Laboratory assessments

Amylase and lipase will be analysed separately with the same type of methods as for pulse with the corresponding baseline assessment as a covariate. The values will be log transformed in the analysis.

Calcitonin

In addition to the descriptive statistics and categorical summary showing number of values in the categories normal, high, >20 ng/L, 50 ng/L and >100 ng/L, all subjects with any post-baseline value of calcitonin above 20 ng/L will be assessed.

Classification of Hypoglycaemia

Treatment emergent: hypoglycaemic episodes will be defined as treatment emergent if the onset of the episode occurs within the on-treatment observation period (see definition of observation periods in Section 2.3).

Nocturnal hypoglycaemic episodes: are episodes with time of onset between 00:01 and 05:59 both inclusive.

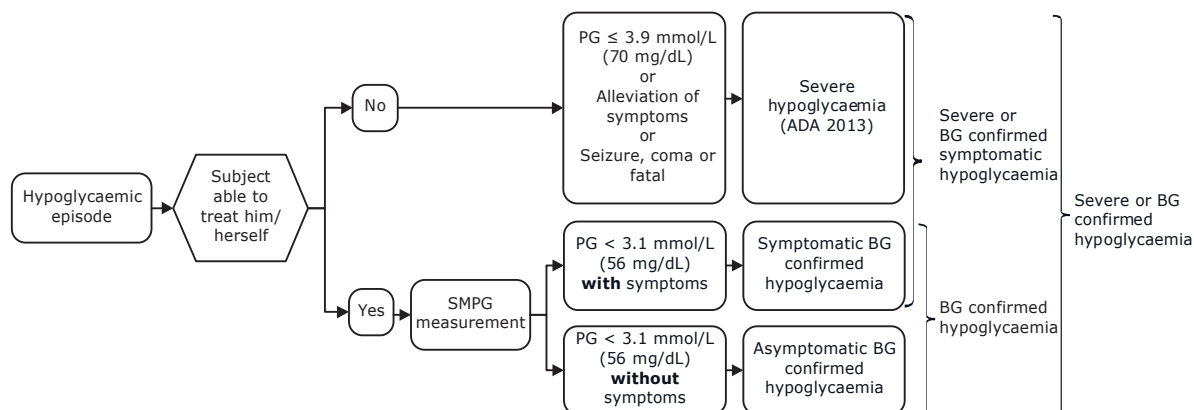

Hypoglycaemic episodes are classified according to the Novo Nordisk classification of hypoglycaemia and the ADA classification of hypoglycaemia (see [Figure 2-2](#)).

Novo Nordisk classification of hypoglycaemia

In normal physiology, symptoms of hypoglycaemia occur below a plasma glucose level of 3.1 mmol/L (56 mg/dL)¹. Therefore, Novo Nordisk has included hypoglycaemia with plasma glucose levels below this cut-off point of hypoglycaemia.

In this trial Novo Nordisk use the following classification in addition to the ADA classification (see [Figure 2-1](#)):

- Severe or BG confirmed symptomatic hypoglycaemia: An episode that is severe according to the ADA classification² or BG confirmed by a plasma glucose value <3.1 mmol/L (56 mg/dL) with symptoms consistent with hypoglycaemia.

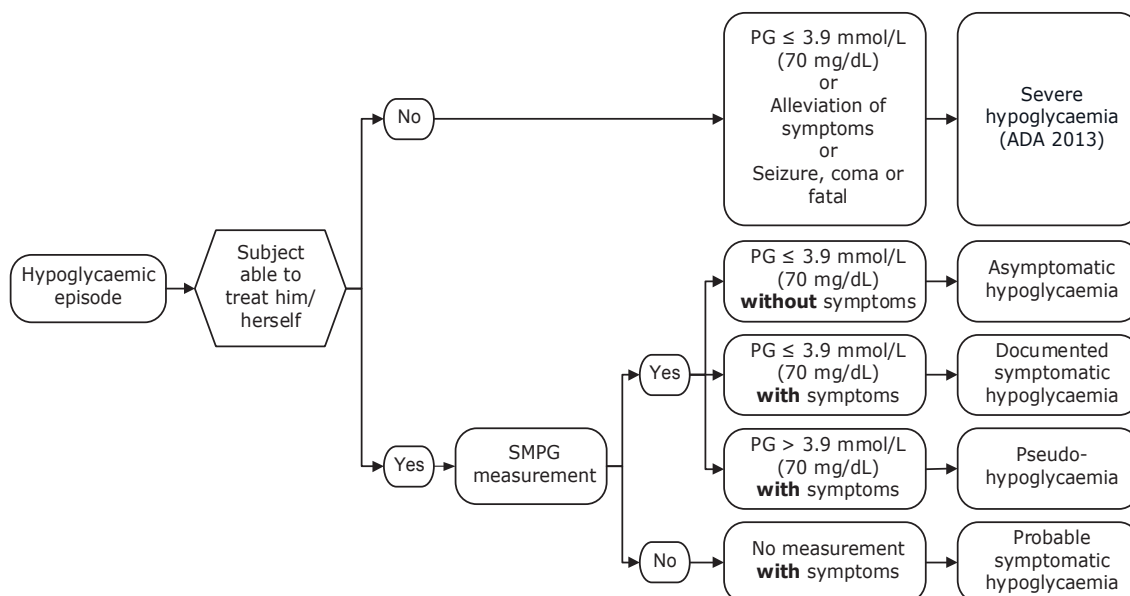

Note: Glucose measurements are performed with capillary blood calibrated to plasma equivalent glucose values

BG: blood glucose PG: plasma glucose SMPG: Self-measured plasma glucose

Figure 2-1 Novo Nordisk classification of hypoglycaemia

ADA classification of hypoglycaemia²

- Severe hypoglycaemia: An episode requiring assistance of another person to actively administer carbohydrate, glucagon, or take of other corrective actions. Plasma glucose concentration may not be available during an event, but neurological recovery following the return of plasma glucose to normal is considered sufficient evidence that the event was induced by a low plasma glucose concentration.
- Asymptomatic hypoglycaemia: An episode not accompanied by typical symptoms of hypoglycaemia, but with a measured plasma glucose concentration ≤ 3.9 mmol/L (70 mg/dL).
- Documented symptomatic hypoglycaemia: An episode during which typical symptoms of hypoglycaemia are accompanied by a measured plasma glucose concentration ≤ 3.9 mmol/L (70 mg/dL).
- Pseudo-hypoglycaemia: An episode during which the person with diabetes reports any of the typical symptoms of hypoglycaemia with a measured plasma glucose concentration > 3.9 mmol/L (70 mg/dL) but approaching that level.
- Probable symptomatic hypoglycaemia: An episode during which symptoms of hypoglycaemia are not accompanied by a plasma glucose determination but that was presumably caused by a plasma glucose concentration ≤ 3.9 mmol/L (70 mg/dL).

Note: Glucose measurements are performed with capillary blood calibrated to plasma equivalent glucose values

PG: plasma glucose SMPG: Self-measured plasma glucose

Figure 2–2 ADA classification of hypoglycaemia

Number of severe or BG confirmed symptomatic hypoglycaemic episodes

Data on treatment emergent hypoglycaemic episodes are presented in terms of the number of subjects with at least one episode, the percentage of subjects with at least one episode (%), the total number of episodes and the episodes rate per 100 years of exposure. Summaries of treatment emergent hypoglycaemic episodes will be presented as an overview including all episodes and episodes by severity.

The summary will include the number of severe or BG confirmed symptomatic hypoglycaemic episodes

Number of nocturnal hypoglycaemic episodes

The number of nocturnal (00:01-05:59 am) treatment emergent episodes will be displayed as described above for hypoglycaemic episodes.

Treatment emergent severe or BG confirmed symptomatic hypoglycaemic episodes (yes/no)

The number of subjects with treatment emergent severe or BG confirmed symptomatic hypoglycaemic episodes (yes/no) including nocturnal severe or BG confirmed symptomatic hypoglycaemic episodes (yes/no) can be assessed from the above described tables.

2.6 Health economics and/or patient reported outcomes

The PRO questionnaires, SF-36v2TM and DTSQs, will be used to evaluate the objective regarding Quality of Life, see Section [2.5.2.1](#) for the details of the corresponding statistical analysis.

2.7 China cohort

In order to assess the effect of semaglutide in the Chinese population all analyses will be done in the same way as described for the entire trial, but only including subjects from region China. For the sensitivity analyses using multiple imputations the imputations for each subject based on the entire population will be used.

3 Changes to the statistical analyses planned in the protocol

The changes to the statistical analyses planned in the protocol are described in the table below.

Change to planned statistical analysis	Rationale for change
A description of the estimand pertaining to the primary objective and primary endpoint has been added. Similarly is done for the secondary objective and confirmatory secondary endpoint. See Section 1.1	Updated for clarification and to be in line with the use of estimands.
It is clarified that the SAP is relevant both for the analysis of data for the entire trial population and for the analysis of the China cohort by it self. See Section 2.1	A separate report describing the results for the Chinese cohort will be made. To clarify that the SAP is relevant for both the report for NN9535-4114 as well as the report for the Chinese cohort, this statement was added
A statement regarding which subjects belong in region China and which subjects belong in region Other was added. See Section 2.1	Stratification was not done by country as specified in the protocol but by region China/Other. Therefore, this specification is needed.
“country” replaced by “region China/Other” in all statistical analyses throughout the document	Due to the change in stratification this change is necessary to comply with ICH E9.
A section describing data transformations has been added. See Section 2.1	Updated for clarification
The completer analysis has been separated from the “in-trial” analysis. Furthermore, a detailed description of the completer definition has been added. See Section 2.4	Updated for clarification.
In the description of the pattern mixture model sensitivity analysis it has been clarified that subjects should have initiated rescue medication or discontinued treatment prematurely to be assumed switched to control treatment. See Section 2.4	Updated for clarification.
In the description of the pattern mixture model sensitivity analysis it has been clarified in bullet 5 that it is subjects with an imputed value at visit 9 (week 30) who will have a penalty added. See Section 2.4	Updated for clarification.
Two extra sensitivity analyses – a tipping point analysis and a retrieved dropout analysis – have	The extra sensitivity analyses have been added to be in line with the sensitivity analyses used

been added to the section regarding sensitivity analyses. See Section 2.4	in recent phase 3b trials investigating the effect of semaglutide s.c.
A table has been added to get a schematic overview of all the sensitivity analyses for the primary endpoint. See Section 2.4	Updated for clarification.
The statistical subgroup analysis of the interaction effect between treatment and country has been removed as well as the evaluation of safety for China and Korea. See Section 2.4	Since the stratification has been changed to be by region China/Other the planned subgroup analysis and safety assessment for China and Korea were less relevant. Furthermore for the Chinese cohort, a separate report including all analyses planned for the entire trial population will be made.
A table has been added to get a schematic overview of all the sensitivity analyses for the primary endpoint. See Section 2.5.1	Updated for clarification.
“data” has been changed to “observation period” in the description on how to analyse supportive secondary efficacy endpoints. See Section 2.5.1	Updated for clarification
Treatment emergent has been added to the definition of “Treatment emergent severe or BG confirmed symptomatic hypoglycaemic episodes during 30 weeks of treatment (yes/no)” and to the definition of nocturnal hypoglycaemic episodes. See Section 2.5.2.2	Updated for clarification
It has been clarified that analysis of pulse is based on SAS instead of FAS. See Section 2.5.2.2	Pulse is a safety measure.
The description of how calcitonin will be reported has been updated. See Section 2.5.2.2	The update is to be in line with how calcitonin was reported in SUSTAIN 2 (trial NN9535-3626) which is the mother trial for NN9535-4114
The analyses of number of severe or BG confirmed hypoglycaemic episodes, number of nocturnal severe or BG confirmed hypoglycaemic episodes, number of subjects with severe or BG confirmed hypoglycaemic episodes and number of subjects with nocturnal severe or BG confirmed hypoglycaemic episodes have been removed. See Section 2.1 and Section 2.5.2.2	The number of severe or BG confirmed episodes is so low that a statistical analysis is not meaningful.
A paragraph describing the analyses that will be done for the Chinese cohort has been added. See Section 2.7	Updated for clarification.
